Environmental Factors & Couple Infertility

Approximately 30% of couples struggling with infertility globally receive a diagnosis of unexplained or idiopathic infertility. This means that despite undergoing extensive tests and evaluations, no clear reason for their infertility can be identified. In essence, it's characterized by the absence of a discernible cause for a couple's inability to conceive.

What is Idiopathic Infertility?

Idiopathic infertility refers to infertility where the cause cannot be identified through standard fertility tests and investigations

Couple & Idiopathic Infertility

Recent research indicates that the human infertility rate is increasing. Although various reasons have been hypothesized for the growing infertility rate, nvironmental contaminants are potentially important causal agents associated with this change.

Each Capsule contains:
